trends differed across trophic levels. Our results show that there are widespread declines in arthropod biomass, abundance and the number of species across trophic levels. Arthropod declines in forests demonstrate that loss is not restricted to open habitats. Our results suggest that major drivers of arthropod decline act at larger spatial scales, and are (at least for grasslands) associated with agriculture at the landscape level. This implies that policies need to address the landscape scale to mitigate the negative effects of land-use practices.

The soil releases a large quantity of carbon that was bound in the past millennia

1950 -> today

50 Pg (*10⁹ t)

of Carbon was released to the atmosphere

Food and Climate

Connecting the Dots

THE PROBLEM

We can't fix the looming climate disaster if all we do is cut fossil fuel emissions.

Even if we had the political will to achieve zero emissions over the next few decades, we would far surpass what scientists refer to as the point of no return—450 ppm of CO₂ in the atmosphere.

DEGENERATED SOILS

- ✘ Have contributed 25-40% of the current excess CO₂ in the atmosphere.
- ✘ Have moved 50-75% of the original carbon content of the earth's soils into the atmosphere and the oceans.
- ✘ Produce nutrient-poor food that contributes to malnutrition and poor health.
- ✘ Grow plants that are less drought-resistant.
- ✘ Intensify rural poverty and hunger, contributing factors to war and civil strife.

ANY USE WINE LABELS?

RUDOLF SILLÉN, NATURVINSAKADEMIEN

According to EU rules from 1979, the wine industry is exempt from presenting content on their bottles. A list of contents is basically prohibited on wine labels. The motive is shrouded in obscurity, but according to my contacts with administrators at the National Food Administration and the Swedish Chemicals Agency, this is due to commercial policy reasons and pressure from strong lobby groups among wine producers. According to the EU, wine is defined as “alcoholic beverage made from fermented grape must from freshly harvested grapes”.

That definition might be true for wines made before the chemical revolution in the 1950s. Nowadays, all wines except natural wines are produced using various chemicals and processes. Some of the chemicals found in the wines are definitely detrimental to health. This applies especially to the systemic pesticides used in cultivating grapes. Many pesticides can occur at levels that are significantly higher than what is permitted for drinking water...

WHAT'S IN THE WINE?

What you learn by reading the bottle label is not a whole lot. Alcohol

er. The highest level found in one of

iciency. On the bottle label, the text “Contains sulfites” must be reported if the content exceeds 10 mg/L. Not particularly informative since the wine can contain anything between 11-300 mg/L. For organic wines, spraying with systemic pesticides is not allowed, and the permitted number of chemicals and processes is limited to about 40. For natural wines, no chemicals are allowed except for minor amounts of sulfites.

WHAT MOTIVES ARE THERE FOR INTRODUCING AN INGREDIENT LIST?

The first motive is the “health as-

Consumers are more and more concerned about health issues

Fungal and bacterial communities
were often enhanced by
organic + green manure management

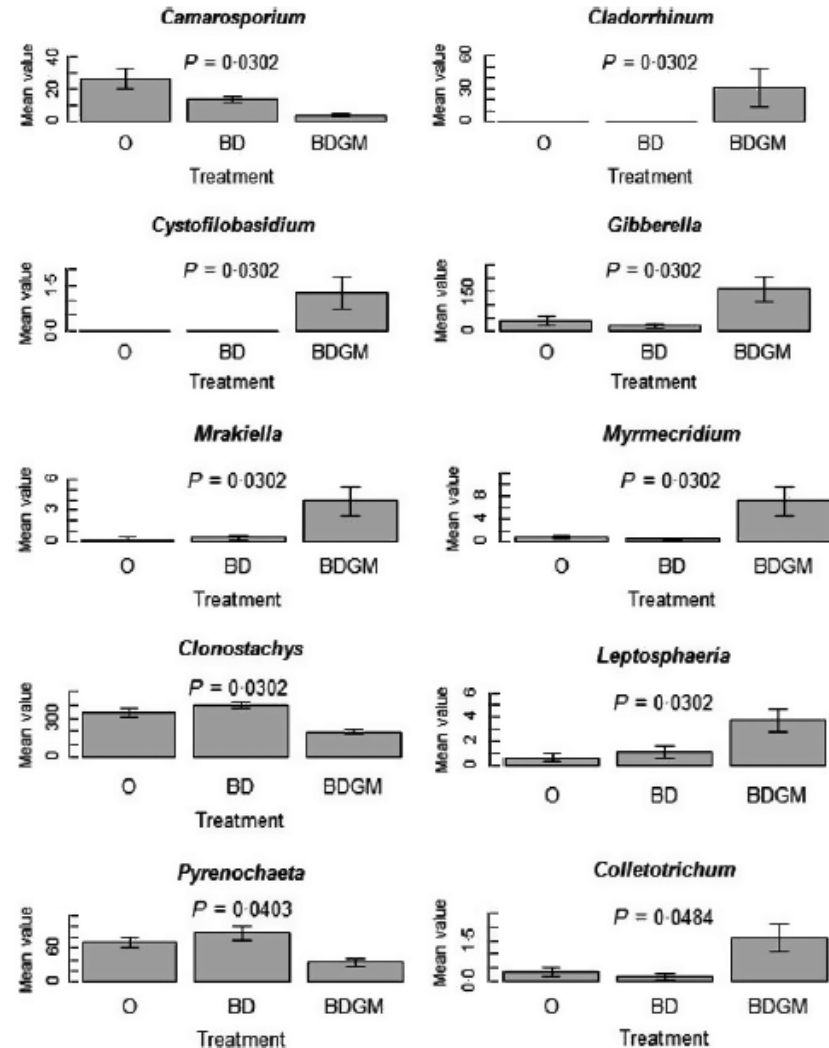

Figure 4 Bar plots of the different fungal OTU abundance at genus level for different types of vineyard soil management obtained via permutation ANOVA. Only significantly different genera (P -values corrected using FDR) are shown (mean \pm SD of number of reads). O, samples from organically managed soil, BD, samples from biodynamically managed soil, BDGM, samples from biodynamically managed soil with the addition of green manure.

Flower strip: the orchard example

Technical guide

2018 | English edition | No. 2003

Functional agrobiodiversity

Perennial flower strips – a tool for improving pest control in apple organic orchards

Soil preparation and sowing of flower strips

Sowing periods

Two sowing periods are possible:

In regions with short winters:

- (i) from April to May and
- (ii) from early September to mid-October.

In regions with long winters:

- (i) in May and
- (ii) in August to early September (after harvest).

Climatic conditions immediately after sowing have a major influence on the result. Sowing between the end of April and early June enables germination of a part of the seeds before summer drought. Further seeds will germinate in the following years.

In regions with frequent dry periods in spring, sowing can be postponed or done in autumn, in order to increase the chance to quickly benefit from a wet period inducing a good germination rate. Late sowing also allows soil cultivation during summer, which reduces perennial weeds and regrowth of grasses. Moreover, lower weed developments can occur during autumn.

Soil preparation

A carefully prepared seedbed promotes good germination and early development of the sown species and reduces later maintenance measures. The goal is to prepare a seedbed reducing the grass competition, so that it will stay vegetation-free at least for four weeks.

The recommended width for flower strips is equal to the inner distance between the tractor wheels plus 10 cm, resulting in a 5–10 cm overlap into the tractor track at each wheel. It depends on the available machinery for soil preparation and mulching.

How to proceed:

- Only work the soil after it has dried well.
- Prepare a relatively fine seed-bed using a rotary tiller/cultivator. Avoid too fine seedbed, as it will silt when it rains and thus hinder emergence of the sown plants.
- Ensure good settling of the soil for four to six weeks to allow a good contact between seeds and soil.
- Before sowing, encourage germination of weed seeds through repeated (two times) superficial (max. 3 cm deep) mechanical harrowing or manual raking. This will reduce weed pressure after germination of the seed mixture.

Procedure for sowing a flower strip and management in the first year

Which landscape do we want ?

Monoculture vineyards

Vineyards with biodiversity

From Vegetation Database to Participatory Landscape Design

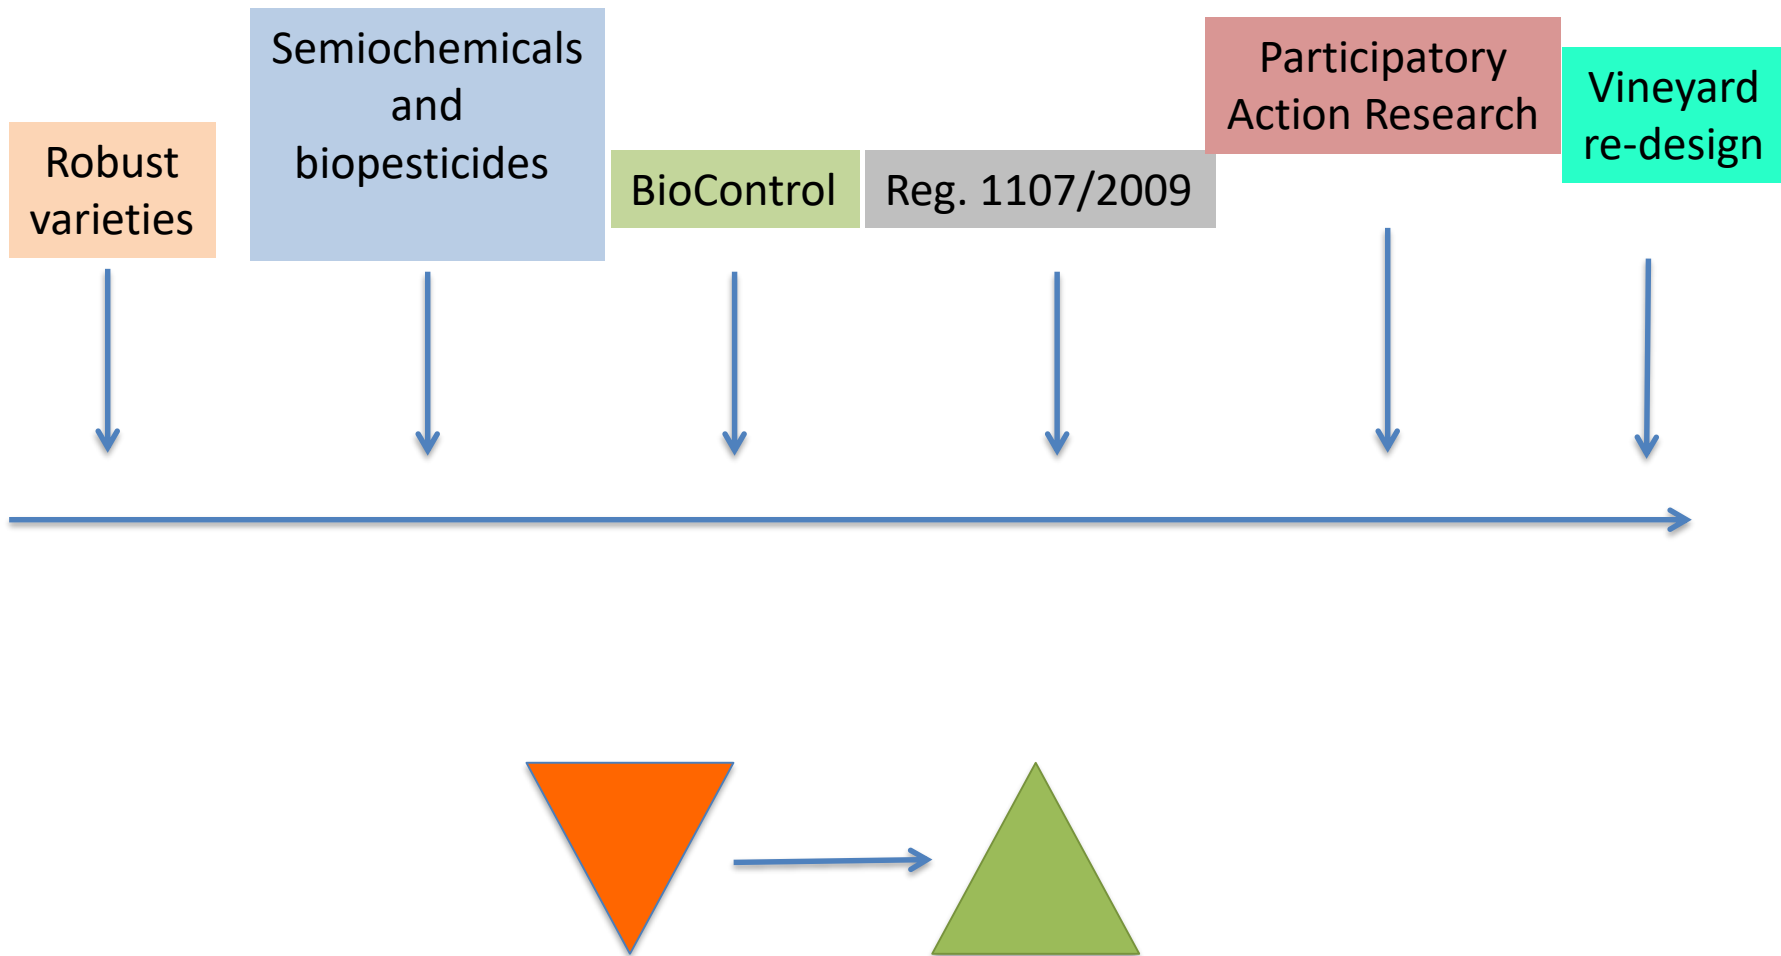

Relationship between landscape and predation/parasitism of pest species in single crops

Integration of multiple maps into a single bio-control service map

My proposal

- **Beyond organic approach (social, ecological and economical aspects)**
- actively involve **farmers**, **advisors**, researchers and local politicians to co-develop (1) a perennial (=permanent) biodiversity structure in the landscape including corridors (2) a field demonstration with disease resistant varieties and (3) field efficacy evaluation of new low risk PPP and the biodiversity structure at a regional level
- promote a new approach to soil management mimicking nature (cover crops + organic matter on the surface as in nature to conserve water, nutrients, carbon and soil life and to reduce soil compactness) (->resilience towards climate change). This will also stimulate soil biota relevant to biocontrol.
- increased support to local natural wine production (especially at the small-to middle scale level) with a view to increase quality and price for growers (to reach a price which gives profit, without eroding the environment)
- higher support to organic and IP farmers operating on hilly terrain, with high associated labor cost

Conclusion: The toolbox for sustainable vineyards

Possible challenges perceived by wine growers

- •Land/space limitations -focus on vines only (when implemented as single farm)
- •Lack of funding to plant/protect habitat and to use cover crops
- •Water or labor limitations for establishing hedgerows
- •May attract vertebrate pests (eg, voles) and their management should be discussed
- •Concern about invasive species (plants & insects, see BMSB in S Italy)
- •Lack understanding of measurable benefits for the society (although many recent publications measured that)
- Higher knowledge required to manage the ecosystem (in comparison with a monoculture)

CERTIFIED SUSTAINABLE Performance Metrics

Mission

The Sustainable Winegrowing Program's mission, vision and values best describe the combination of factors that motivated the California wine community to design, develop, implement and report on a comprehensive sustainability program.

The long-term mission for the Sustainable Winegrowing Program includes:

- Establishing voluntary high standards of sustainable practices to be followed and maintained by the entire wine community
- Enhancing winegrower-to-winegrower and vintner-to-vintner education on the importance of sustainable practices and how self-governing will enhance the economic viability and future of the wine community
- Demonstrating how working closely with neighbors, communities and other stakeholders to maintain an open dialogue can address concerns, enhance mutual respect, and accelerate results

Vision

The vision of the Sustainable Winegrowing Program is the long-term sustainability of the California wine community. To place the concept of sustainability into the context of winegrowing, the program defines sustainable winegrowing as growing and winemaking practices that are sensitive to the environment (Environmentally Sound), responsive to the needs and interests of society-at-large (Socially Equitable), and are economically feasible to implement and maintain (Economically Feasible). The combination of these three principles is often referred to as the three "E's" of sustainability.

These three overarching principles provide a general direction to pursue sustainability. However, these important principles need to be translated into the everyday operations of winegrowing and winemaking. To bridge this gap between general principles and daily decision-making, the Code of Sustainable Winegrowing Practices workbook's 15 self-assessment chapters translate the sustainability principles into specific winegrowing and winemaking practices.
